

These four edges are the loop: a block now tightens a *later* call in the same session.

Party crossings (data changes hands): ① ingress ② model ④ egress

Internal gate ③ authorization + integrity: a decision inside the trusted region. It admits or refuses a flow; it never moves data across a boundary, which is why it is drawn on the path rather than at an edge.

Content goes through the model. Labels go around it. That is why a decision at ④ can read what ① established.
